Problem $\mathcal{X}$: A city museum planned a weekend exhibition with three rooms: the East Hall, the Garden Room, and the Archive Room. At first, the curator wanted to place the photography exhibit in the East Hall because it has the brightest natural light. However, the East Hall was later reserved for a school art workshop that required movable tables and open floor space.

The **Garden Room** was available, but the maintenance team warned that its ceiling had a minor leak during heavy rain. Because the forecast predicted storms on Saturday afternoon, the curator decided that fragile paper materials should not be placed there. The Archive Room had no windows, but it had stable humidity control and locked display cases.

The **photography exhibit** used framed prints, while the historical-letter exhibit contained original paper documents from the 1890s. The children’s sculpture activity used clay models and washable tools, and it needed tables rather than display cases. On Friday evening, the museum director asked the curator to avoid any room changes after the public schedule was printed.

By the final plan, the school workshop stayed in the East Hall, the historical-letter exhibit was moved to the **Archive Room**, and the photography exhibit was placed in the Garden Room. The sculpture activity was held next to the school workshop, using the same tables after the workshop ended.

Question: Why was the historical-letter exhibit moved to the Archive Room instead of the Garden Room, and why could the photography exhibit still use the Garden Room?
